

S P E C I F I C A T I O N

MACHINE READABLE LABEL READER SYSTEM FOR ARTICLES WITH  
CHANGEABLE STATUS

BACKGROUND OF THE INVENTION

5 Field of the Invention

The invention relates to systems that employ machine-readable labels to store data and deliver them to readers when scanned. Examples include one- and two-dimensional bar-codes, memory buttons, smart cards, radio-frequency identifier (RFID) tags, smart cards, magnetic stripes, micro-chip transponders, etc.

Background

Various devices for encoding data currently exist and are under development. These take many different forms, from optical devices such as two-dimensional bar-codes to radio devices such as transponders. These devices generally permit objects to be tagged or labeled to permit machines to read data associated with the object. One-dimensional bar-codes have been used widely for this purpose, but they are limited in terms of how much

information they can store. For example, they can identify classes of objects, but not individual objects.

A recent entrant to this field, radio-frequency identifier (RFID) tags, delivers information by radio signals to a reader just as a transponder does. One of the attractions of RFID devices is their potential to carry a large quantity of information. This is in contrast to conventional bar codes whose data capacity is much more limited. Another alternative to conventional bar-codes are two-dimensional bar codes. These are two-dimensional symbols that are capable of encoding much more data than a conventional bar-code. Another encoding device is the iButton®, a small token that stores information that can be read by a reader that makes electrical contact with the iButton®. Still other devices for storing information include printed and non-printed (e.g., etched) machine readable symbols (e.g., using a pattern recognition process) and digital watermarks.

Commercial applications of RFID technology are expected to be highly successful. Supply chain management is one of the biggest. Plans are for manufacturers to register each product's serial number in a database that could be accessed during the product's journey through the

supply chain. By keeping the data on a network resource  
such as a server, a service provider could enable stores or  
warehouses to use a portable scanner to check the history  
of the product. Retailers thus could check for authenticity  
5 or theft, as well as monitor out-of-stock and out-of-demand  
trends. RFID tags may be programmable and may also include  
sensors that can record, right in the tag, various  
environmental factors such as the amount of time a crate of  
fruit was held at a given temperature.

10 An obvious model for a future consumer market for  
RFID tags is the present consumer market for bar-code  
readers. While bar-code readers have been widely adopted  
by commercial and industrial users, so far, attempts by  
manufacturers and vendors to develop consumer markets have  
15 met with very limited success. Some examples of consumer  
applications, current and future, are discussed below.

One example of a bar-code reader product aimed at  
consumers is the Cue Cat®, a reader designed to be  
installed on a computer and used to read bar-codes printed  
20 in catalogues, magazine advertisements, and product labels.  
When a user scans a bar-code, the code is automatically  
conveyed through the Internet to a server that points the  
user's browser to a web site for that particular bar-code.

The user is saved the trouble of typing in a web address, which could conceivably be a long one if every product had its own web address, but the benefit is not much greater than that. Also, web addresses can be generated for  
5 existing products (like a year-old can of peaches in the cupboard) without the user having to look one up (such as by searching with a search engine). If the maintainer of the Cue Cat® service fails to provide a link for a product, users can suggest a web address. Another similar proposed  
10 application is bar-codes on coupons that take the user to a 'bonus coupon' section on a web site.

Another proposed application is recipe books with bar-codes that a user can scan and automatically generate a shopping list for the grocery store. The user chooses what  
15 to purchase by scanning bar-codes on labels of products at home. From this, a service generates a shopping list to take to the store and use as a dietary guide. Using a cordless barcode scanner the user scans barcodes on boxes or wrappers of grocery items to add them to the user's  
20 shopping list. The scanner is synched to a computer before shopping, and by means of an Internet connection, the personalized shopping list is generated and printed out.

The shopping list includes healthy suggestions for the

items on the list that are identified as similar to what was originally scanned, but more consistent with the user's specified dietary goals. Categories such as less fat, less sodium, fewer calories or other options are provided for.

- 5 The list is broken down into two columns, one containing suggested choices and one with the items originally scanned. An explanation of why this food item is better is provided for each item. An indication is also provided for how close the original item is to the system's best choice
- 10 for the class of product. A recipe icon next to some items cues the user to click on links for recipes that use the items on the shopping list and conform to the nutritional profile. For grocers that subscribe to a service, coupon offers can be entered on the shopping list and even
- 15 downloaded to the user's shopper's loyalty card file.

- Portable readers are used, or proposed to be used, in various other applications. For example, a consumer can maintain an inventory of bar-coded valuables, such as bicycles, camcorders, cars, etc. Another
- 20 application allows users to scan items at participating retailers and build a "wish list" that they can post to a personalized web page. The list can be organized and emailed to others for gift-related occasions. Shoppers

register at a mall kiosk, set up a password, and check out  
a scanner. Shoppers then build their "wish list" by simply  
scanning bar codes of items. The data is then downloaded  
to the kiosk when the scanner is returned and the wish list  
5 is posted to the web site. Yet another application, which  
is very similar to the Cue Cat® is the idea of placing a  
bar-code on a movie or sporting event ticket stub. The  
bar-code, in Cue Cat®-fashion, brings the user to a web-  
site automatically, allowing the user to purchase products  
10 relating to the event, such as sports memorabilia or movie  
sound-tracks. Yet another, offered by AirClic®, uses bar-  
codes attached to print articles to bring the user to a web  
site giving access to updated information, purchase  
opportunities, or other web features relating to the  
15 article. The technology is envisioned as being  
incorporated in handy appliances such as a cell phone, so  
the user does not need to be near a computer to use it.

The above examples illustrate various attempts to  
find consumer applications for their products. Most of  
20 these are one-off (specialized) ideas and confer little  
benefit over traditional ways of accomplishing their  
respective tasks. The wish list application is highly  
specialized, as are the grocery shopping list application

and the home inventory application. With bar-codes being as pervasive as they are, it is surprising that nobody has come up with truly useful ways of using them, at least for consumers. As discussed above, one component of a break-through may be to increase the amount of data that can be stored on bar-code or other types of data storage vehicle. While this, by itself, will not make "killer applications" roll off the tops of designers' heads, many benefits arise in connection with the increased data capacity of RFID tags and other technologies for storing larger quantities of data than traditional bar-codes.

Unlike bar-codes, which can encode only enough data to correlate a small amount of information, some machine-readable label (MRL) devices can store enough information to accomplish some very interesting things. For example, if attached to a product, it can uniquely identify that particular product, which could be tied in a central database to its date of manufacture, the shipment vessel it was conveyed in, its date of shipment, the retailer to whom it was shipped, to whom it was sold, how it was manufactured, when, etc. Also, some MRL devices can also be programmed to change the data stored in them, as, for example, does the temperature sensing supply chain

application mentioned above. Another advantage is that some are capable of being scanned by holding a reader some distance away and without precisely aiming the reader with respect to the MRL device. Some readers are capable or  
5 reading many MRL devices at once, for example RIFD readers.

Generally, MRL devices have been rather expensive, so few applications have been developed for the consumer market. An example of a system aimed at consumers, which is not greatly affected by cost, is a  
10 supermarket system for promoting products. In this system, a user picks up a shopping cart equipped with a portable radio terminal. As the user browses the aisles, he/she passes certain radio transmitting stations that have been set up to promote products shelved near those stations. As  
15 the user nears each such station, the portable radio terminal receives a message from the station and begins to play a promotional graphic and/or text message with attending sound. The graphic and text/audio messages are derived from some other source, such as a network server to  
20 which the terminal is wirelessly connected. The station transmits a unique identifier that prompts the terminal to deliver the graphic and text/audio message corresponding to the identifier. Similar applications are expected to

appear in a greater range of contexts as the costs of high density MRL devices come down.

Research projects, such as at Massachusetts Institute of Technology (MIT) Media Lab, have explored using RFID tags to automate many activities. For example, one project resulted in the construction of a coffee machine that could read the identity of the owner of a coffee mug placed for receiving coffee. Using this information, the machine made the particular type of coffee favored by the mug's owner and played music preferred by him/her. Another application proposed by the Media Lab is a refrigerator which reads the RFID tags of its contents, thereby maintaining an inventory. Another example was a microwave oven that gave instructions to the user and programmed itself for the type of food (given by an RFID tag) that was to be cooked. These systems are envisioned as being part of a household network with all manner of input and output devices, all of them intelligent and environment-responsive. The refrigerator knows what the oven is doing. Ovens, sinks, etc., all know their contents, status, and are enabled to act on objects both physically and digitally. The cupboards can advise a user as to whether s/he has all the ingredients you need to make

a recipe. The kitchen observes the user making the recipe and gives advice synchronized with the user's activity.

A white paper written by Joseph Kaye of MIT Media Lab proffered a number of concepts relevant to the

5 environment of the current invention. One concept is for everything to be connected. For example, the RFID tag on a Tupperware container informs a reader in the sink that the container is being washed and is therefore empty. The food that had been stored in the container was removed and the  
10 container emptied. A particular food had previously been associated with the container's RFID tag by the refrigerator which "asked," when the container was put into the refrigerator, for information on the container's contents. The contents were thereafter part of the food  
15 inventory until the container was emptied. A smart kitchen envisioned by MIT Media Lab helps a user cook by guiding the user through a recipe, recommending substitutions, and telling the user where to find ingredients. Mr. Kaye also suggests identifying all products uniquely and providing  
20 each with an individual web page, available from which is every detail of that particular product's history.

There is a need in the current state of the art for applications of code-reading devices which provide real

benefits that consumers will want and to provide these  
benefits with a minimum of hassle so consumers will adopt  
the applications.

5

## SUMMARY OF THE INVENTION

10

15

The invention is designed for an environment in  
which inexpensive machine-readable label devices ("MRL  
devices") appear in a great variety of contexts, as do bar-  
codes presently. In the future, high data-density MRL  
devices may appear on purchasable products, ticket stubs,  
advertising media, shipping containers, delicatessen  
containers, etc. Readers of MRL devices may also  
proliferate. For example, they may be found in portable  
devices such as personal information managers (PIMs), cell  
phones, or cross-over devices. They may also be found  
incorporated in many common fixed appliances such as cash  
registers, publicly-accessible kiosks, domestic appliances,  
TV remote controls, etc.

20

Although a world full of high data-density MRL  
devices and readers is forecast by many technology-  
watchers, this will only happen if such devices provide  
real value to users. The present invention is concerned  
with several barriers to reaching this goal. One barrier

is the demands any new technology makes on users. Users do not like to adopt new ways of doing things, unless there is a big payoff. Making technology that is easy to use as well as useful often means complex programming. Another  
5 barrier to widespread consumer acceptance is the difficulty of providing information and/or services that are truly useful to the user in a wide array of different contexts rather than simply a small number of narrow contexts.

One way to make MRL applications easy to use is  
10 to insure that they only present to the user those pieces of information and services that are relevant to the user. That way, the user is not required to navigate menus or enter additional information to get to something useful. To do this, preferably, the user's immediate circumstances  
15 and preferences need to be taken into account. Most wireless applications are built with very little capacity for personalization, although this is an important design element for web portals that users return to again and again. The goal of the present invention is to provide a  
20 system that users will turn to repeatedly in many contexts, including new ones, because they have the experience that the system usually provides valuable information and/or services with a minimum of hassle. At the back end,

another goal of the system is to provide this utility with a minimum of difficulty for programmers to provide the services.

The invention provides mechanisms by which a MRL  
5 reader may deliver highly relevant information or processes relating, in some way, to an article to which a MRL device is attached, taking into account other circumstances relating to the user such as the user's personal preferences, the user's environment, etc. The invention  
10 also provides mechanisms for sifting through the large quantity of potentially relevant information or number of resources and identifying those that are most likely to be the best choices for the user, thereby avoiding making demands on the user. Further, the invention provides  
15 mechanisms for insuring that the reader never produces useless responses even when confronted with requests that are impossible to predict, such as a user scanning a cereal box with a table-saw reader. Still further, the invention provides mechanisms by which a portable reader can still  
20 provide utility even when not connected to a database that can decode the MRL data.

Making intelligent use of many available sources of information about the user and his/her status and

context of use at the time a request is made (compactly,  
the "user state") is an onerous programming task because of  
the many possible system responses. In addition, even  
without the issue of how to connect the many possible user  
5 states to many possible responses, it can be difficult on  
its own to provide the large numbers of responses that are  
connectable with the possible user states.

To this end, the invention leverages advances in  
search engine technology. New search engine technologies  
10 allow users to specify requests in natural language in  
order to access large unorganized corpuses of data (web  
pages). These technologies have the potential for being  
adapted to use in MRL systems. This makes it possible to  
create response data in a relatively unstructured format,  
15 relying on sophisticated search engine technology to  
determine how to connect requests to the most appropriate  
information or services in a resource database.

With a robust and flexible strategy in place for  
leveraging all available user state information, it is  
20 easier for new functionality to be added. For one thing, a  
service provider who creates a resource database does not  
need to script a response for each anticipated situation.  
This makes the task of adding new responses to a response

database less onerous. For another thing, a single  
situation may admit of a variety of different responses.  
The usual way of handling that is to give the user a  
choice. By using the robust strategy suggested here, the  
5 system can filter the multiple of potentially applicable  
responses, avoiding the need for the user to make the  
choice in subsequent steps. The user receives the desired  
response faster and with less hassle. Readers affixed to a  
particular object, such as a home appliance, may transmit  
10 information identifying the particular object to the  
information resource. For example, the microwave oven may  
identify its make and model number to the information  
resource before receiving programming instructions. By  
providing the information resource with specific details  
15 about the context of the request for information (e.g., "I  
am a microwave oven, located in a residence, and I am  
requesting information about this particular frozen  
dinner."), the information resource can make its response  
as relevant as possible ("You must want programming  
20 instructions.") Without the particulars of the context, it  
might take several exchanges between a user and the  
information resource before the relevant information was  
delivered. For example, the user could be shopping and

simply want to know something about the product in  
anticipation of purchasing it. Without the context, the  
situation is much like visiting a worldwide web (WWW) site  
today, where it is necessary to navigate a menu tree before  
5 the desired information can be found.

Given that additional information supplied to the  
information resource can increase the relevance of  
responses, readers may be programmed to deliver information  
regarding the requesting user. For example, a personal  
10 reader may store a user profile or access a user profile  
stored on a network (or Internet). The benefit of the  
latter is that it further allows the responding information  
provider to personalize its response, increasing the odds  
the user will act on the information supplied. This  
15 personalization data can be transmitted from the reader or  
derived by the information provider from another server  
storing such data according to a unique identifier for the  
personalization data.

Other sources of information that may be used to  
20 increase the relevancy of responses include stored  
historical use patterns/preferences, general data such as  
news, weather, time of day, season of the year, and  
information from other resources such as an inventory

stored on a local network server. Here is an example of  
how such data could be used. An individual scans a MRL  
device affixed to a frozen dinner with a microwave oven  
reader. The local time of day is 8:00 AM, so it is less  
5 likely the user is planning to cook the frozen dinner at  
this time. Historical use patterns indicate that the user  
has never programmed the microwave oven to cook frozen  
dinners in the morning. The household inventory, stored on  
a server to which the microwave oven reader is connected  
10 through a network, indicates current level of frozen  
dinners is one unit. It is currently winter, and  
historical use patterns indicate that frozen dinners are  
cooked frequently during the winter months. The microwave  
oven reader transmits relevant information to an  
15 information resource, in this case an Internet server  
indicated in the MRL device, and receives a menu with  
several options, responses to each of the options being  
included in the transmission. The options include an  
identification of a local store at which frozen dinners are  
20 on sale, similar products the user may want to try, and  
instructions on how to heat a large number of frozen  
dinners for a dinner party. If it had been dinnertime, the

information resource might have returned simply cooking instructions.

Another issue that relates to the potential for widespread acceptance of MRL devices is that people are less likely to adopt the habit of using new technology, especially when its use requires adaptation, when the technology is usable in only certain circumstances. So, for example, if only some products purchasable at a supermarket were fitted with MRL devices and others not, consumers would require two different ways of performing the tasks that the MRL devices otherwise automate: one for articles fitted with MRL devices and one for articles not so fitted. Thus, for example, MRL devices have the potential to automate the tracking of food inventory, the making of shopping lists, and the determination of the sufficiency of on-hand goods for making a recipe. If, however, only part of a shopping list can be made, or only half the requirements for a recipe automatically determined, the utility of such automation is greatly diminished. Thus, according to certain features of the invention, MRL devices may be provided for articles that are not prepackaged, such as consumables like delicatessen goods, produce, meat, etc.

While it has been proposed that MRL devices and bar-codes be used to connect users to web sites for purchase of goods, this degree of automation merely avoids the need for the user to enter a web address. This idea is basically the same as the Cue Cat<sup>®</sup> system. Since machine-readable symbols like MRL devices can bring users to a web site quickly, they have the potential to facilitate impulse-purchasing. There is a much greater likelihood of a sale when a user is provided an opportunity to buy a movie soundtrack just as the user leaves the movie with the music still fresh in his/her mind. This could be done by placing an Internet terminal in a self-service kiosk at the theater. The smaller the number of steps involved, the more likely a sale will be completed. In an embodiment of the invention, a MRL device is attached to a ticket stub. The device may contain an address at which the movie soundtrack can be purchased. Moreover, the device contains sufficient data density to correlate or store account, authorization, shipping, and authentication information to allow the purchase to be completed without any prompting from the user aside from the selection and confirmation of an item to be purchased. If a theatergoer purchases tickets using a credit card, the account can be linked

temporarily to data on the MRL device on the ticket stub.

This data can further link an order process to preference information contained in user-profile database and the purchase used to augment that database. To protect the

5 user's account, the connection between the user's credit account and the ticket data may be given a predefined expiration period, say 2 hours after the movie or other event is over. As an inducement for the user to purchase at the theater, the user can be given a discount incentive

10 such as lower price on his/her next ticket purchase, discounted price for the goods ordered, or a free gift.

Precisely the same functionality can be provided through a portable terminal rather than a kiosk terminal or a home computer connected to the network; or even a portable  
15 computer or terminal.

The invention will be described in connection with certain preferred embodiments, with reference to the following illustrative figures so that it may be more fully understood. With reference to the figures, it is stressed  
20 that the particulars shown are by way of example and for purposes of illustrative discussion of the preferred embodiments of the present invention only, and are presented in the cause of providing what is believed to be

the most useful and readily understood description of the principles and conceptual aspects of the invention. In this regard, no attempt is made to show structural details of the invention in more detail than is necessary for a  
5 fundamental understanding of the invention, the description taken with the drawings making apparent to those skilled in the art how the several forms of the invention may be embodied in practice.

## 20 DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Referring to Fig. 1, a MRL device T is prompted by, and transmits data to, a portable reader 100 or a fixed terminal 120 with an integrated reading device. Note that

the reader 100 may be integrated into another appliance,  
such as a personal digital assistant (PDA) or cell phone or  
other. In an embodiment, the MRL device T is a radio  
transponder that generates RF links 110 with readers  
5 100/120. The RF links 110 may be momentary according to  
known transponder technology. Alternatively, the links 110  
may represent data transfer corresponding to any high data  
density transmission method including scanning of printed  
symbols such as two-dimensional bar-codes, contact reading  
10 of a memory token such as an iButton® or smart cards, or  
reading of a magnetic stripe on a surface. The particular  
medium is independent of some aspects of the invention.

The portable reader 100 and fixed terminal 120  
may be linked to a network or the Internet 130 by wireless  
15 and/or wired links 112 and 114, respectively. Also  
connected to the network/Internet 130 are one or more  
network servers 140, which may be operated by commercial  
services. A local area network (LAN) 160 is connected  
through a LAN server 150 to the Network/Internet 130. The  
20 LAN 160 connects the LAN server 150 to various devices  
including a computer 190, and various smart appliances 170-  
185 including a television 175, a microwave oven 180, a  
table saw 185, and a refrigerator 170.

The smart appliances 170-185 are all network-enabled, meaning they each have a microprocessor and at least an input or output device to communicate with a user. For example, the table saw 185 may be enabled to receive software from the Internet to permit it to implement a safety feature or the microwave oven 180 may have a terminal, including a display and keyboard, for displaying recipes taken from the Internet. Smart appliances are discussed widely in the published literature and are not discussed in further detail herein. Each of the smart appliances 170-185 may be equipped with a fixed reader (not shown separately) capable of reading the MRL device T. Data may also be transferred from the portable reader 100 to a device such as the computer 190 by a temporary wired or wireless connection 195 as used for synchronizing data on personal digital assistants and notebook computers. When the reader of a smart appliance 170-185 or home computer 190 reads a MRL device T, it may interact with the user responsively to data in the device and to various data stored on the LAN server 150, the computer 190, or on the network server 140.

Referring to Fig. 2, the MRL device T may be affixed to any article, for example, a product package 225.

Alternatively, the MRL device T may be attached to a shelf unit or case (not shown) near the product package 225. The essential feature is that there is some physical or abstract association between an article and a MRL device.

5 A consumer encountering the product may hold the portable reader 100 close to the MRL device T of the product package 225 and activate the reader 100 to read the MRL device T.

In response, the MRL device T transmits data stored in the MRL device T of the product package 225 to the reader 100.

10 The reader 100 may then transmit the data acquired from the MRL device T, along with other data in its memory M, through the network/Internet 130 to the network server 140 and/or the LAN server 150. Alternatively, a consumer or

15 checkout clerk, during purchase, may scan the MRL device T of the product package 225 using the fixed terminal 120 in a similar manner. The fixed terminal 120 may then transmit the data acquired from the MRL device T, along with other data stored within the fixed terminal 120 or, more likely, in a (e.g., retailer's) server (not shown) connected

20 through the LAN/WAN 135, through the network/Internet 130 to the network server 140 and/or the LAN server 150.

Note that when a MRL device is associated with multiple units, it may be more convenient for it to operate

at a distance. For example, a shopper's portable reader passing by a shelf unit with 40 cans, each with a MRL device T, would receive a barrage of data. But if a single MRL device on a shelf "spoke" for an entire group, it would  
5 be convenient for the shopper's reader to receive data continuously and at a distance. In such a case, the reader's programming may permit passive scanning and allow a user profile to determine if the user should be notified. See discussion referring to Fig. 28 infra.

10 Referring now to Figs. 3 and 4, a MRL device T may be affixed to a variety of articles other than purchased or purchasable goods. For example, the MRL device T may be affixed to one side of a ticket 205 such as a train, movie, show, airline, or other kind of ticket.  
15 Alternatively, the ticket may be a coupon, a receipt, or any other type of article associated with a service or product. The ticket, receipt, etc. 205 may have text 210 on it explaining, for example, a promotion of which the user can take advantage by scanning the MRL device T and  
20 taking some action accordingly. Referring to Fig. 5, similarly, an advertisement 215 such a billboard, a poster, a magazine advertisement, or other such medium may have a MRL device T affixed to it for the same purpose.

Referring to Figs. 1 and 6A, a process that may be implemented based on the hardware environment of Fig. 1 allows a user to receive targeted promotional information through a fixed terminal 120 or portable reader 100 while shopping, for example. Assume the user chances upon a display, advertisement, or purchasable product and is interested in purchasing or learning more about it. For example, the object could be a movie billboard and the user wishes to determine where and when the movie may be seen or to read a review. For the other example, the object may be a food product and the user wishes to know further nutritional information about it or how it can be prepared for eating. The user scans the MRL device T causing the reader 100/120 to acquire data from the MRL device T in step S1.

In step S2, an interaction may be initiated between the reader 100/120 and the LAN server 140 or Network server 140 beginning with the transmission of data to the network server 140. For example, the data transmitted may include data from the MRL device T plus other information, the other information including, for example, the identity of the user and/or certain profile data characterizing the user. Included with the

information from the MRL device T may be a network address  
to which the reader 100/120 may connect to complete the  
information exchange. The interaction is continued as  
defined by an interaction process running on the server 140  
5 at step S3. The data exchanged in the interaction may  
include data responsive to the acquired data, further user  
input S4, and/or data stored on the network server 140.  
Generally, it is contemplated that the interaction would be  
conducted in accord with, and by means of, a client-server  
10 process, for example using HDML (handheld device markup  
language), a markup language for small wireless devices or  
HTML (hypertext markup language).

Profile data characterizing the user may be  
obtained from the servers 140/150 in various ways. The  
15 reader 100/120 may store this information. Alternatively,  
the user may have a unique identifier that is correlated  
with profile data stored on the network server 140  
belonging to the owner of the network address stored in the  
MRL device T. Still another alternative is for the profile  
20 data to be stored on a third party network server 140 with  
which the owner of the addressed network server 140 has a  
relationship.

To give an example of an exchange, imagine that a shopper scans a pair of tennis shoes at a department store. The user's reader 100 acquires a unique identifier from the MRL device T, a unique identifier indicating the owner of the reader 100, and an address corresponding to the network server 140. The reader 100 then transmits these data to the network server 140. The network server 140 runs an interaction process that receives these data and identifies a subprocess that corresponds to the received data. For example, the network server 140 might be owned by the manufacturer of the tennis shoes. The interaction process may look up information about the particular pair of tennis shoes whose MRL device T the user scanned, the date of manufacture, the style, the store to which it was shipped, and so on. The interaction process may also acquire personal profile information about the user from its own internal database or a subscription to a third party database stored on a further network server 140. The personal profile information may contain such data as the style (contemporary or traditional), amenability to participant sports and type of sports, color preferences, etc. Included among the information about the particular pair of shoes may be, for example, that they came from a

lot that has been recalled. The interaction process may  
also retrieve information indicating that the quality of  
the shoes is not consistent with previous purchase patterns  
of the user. The interaction process may also retrieve  
5 information indicating that the user plays other sports  
than tennis. In response to all this data, the interaction  
process may be defined such as to generate an up-selling  
recommendation by suggesting a higher quality type of shoe.  
Further the interaction process may be such as to generate  
10 a cross-selling promotion indicating to the user that the  
particular store to which the shoes were shipped is having  
a sale on tennis racquets (the reasoning behind the  
programming of the interaction process being the conclusion  
that the user is new to tennis and may need the equipment).  
15 The interaction process may be a very simple one,  
consisting of the generation of a single message promoting  
a product, for example. Alternatively, the interaction  
process may request feedback from the user as in step S4.  
For example, it may provide a menu with a number of options  
20 that may be generated on the display of the reader 100/120.  
For convenience, the user may be given the option, outright  
or in the course of the dialog process, of marking certain  
information, or even the entire interaction process, for

later review and completion. Alternatively, the user may be given the option of receiving the data by email or having it stored locally on the reader 100/120 for later review and interaction in the way one currently may save an HTML file locally and interact with links within it when connected. After the reader accepts input in step S4, it may continue an interaction iteratively until completed depending on the incidence of scan events in a status monitoring loop at S5.

Referring now to Fig. 6B, at the server side, the interaction begins at step S55 with the receipt of data from the reader 100/120. The appropriate dialog process is selected at step S60 and begins at step S65 accordingly. The data received at step S55 may include directives from the user such as a preference that any selling information be sent to him/her by email or simply discarded.

Inputs may be matched to responses using various information retrieval techniques used for matching search templates to information resources such as documents or interaction processes. The area of information retrieval is a vast and fast-growing technical area, a detailed discussion of which is outside the scope of the present specification, except as indicated herein. Note that the

term "resource retrieval" might be more apt to describe the invention because the response desired may not simply be a static piece of information, but a process, such as an interaction with the user or a control function such as used for programming a microwave oven. The WWW currently provides ample examples of processes that are retrievable by searches, such as equipment control, transaction, monitoring, etc., so this point need not be elaborated upon.

In prior art bar-code readers and RFID tag reader technology, the process of matching responses stored in a resource space to the context of a scan event focuses either on the article to which the bar-code or RFID tag is affixed or the device to which the reader is connected. In other words, none displays an ability of one reader to perform multiple tasks based on the combination of variables, at least including the type of reader and the type of article identified by a MRL device. This ability may be called "context versatility." Here is a representative list of examples of prior art concepts. Most of these call up a resource, such as a web site, and then require the reader to navigate a menu tree to get to the desired result.

- Portable bar-code reader used to order a product, get directions to a store, make reservations, by scanning a bar-code in a magazine, newspaper, brochure, or other printed advertisement.
- Scanning bar-codes in a catalog to fill an online "shopping cart."
- Scan a bar-code and have further information routed to you by email.
- Order film soundtrack, sports memorabilia, etc. from a bar-code printed on ticket stub.
- Obtain competitive pricing after scanning a SKU or order items related to the article identified by the SKU.
- Cue Cat® - Scan a label and a server connects a web browser directly to a site corresponding to the label. No context responsiveness.

The above examples are all entirely dependent on the bar-code scanned and the data entered (e.g., a menu) by a user. This simply corresponds to the automatic linking of a terminal to a particular web site. The next items do provide context-responsiveness in a sense, since in each

one, a particular response is generated by a particular reader. But these are blue-sky proposals or research projects and the papers on the subjects provide scant information on how the results would be achieved or context-versatility.

- Scan an RFID tag on a frozen dinner with a microwave oven reader to program the microwave oven for that particular frozen dinner.
- Scan the contents of a refrigerator with a refrigerator reader to update household food inventory.
- Determine the contents of cabinets in a kitchen by scanning RFID tags of items, such as pots, etc.
- Place a coffee cup in a coffee maker and the coffee maker plays music and makes the particular kind of coffee preferred by the user designated by a RFID tag built into the cup.
- A system that gives instructions for a recipe while the user is making the recipe. The system advises on substitutions based on personal preferences of the user or

availability of ingredients in the household  
inventory.

In these examples, the response of a system is  
not dependent upon the MRL device contents, but on the type  
5 of reader. For example, a kitchen cabinet reader would  
update the household inventory, but presumably a register  
reader would create a register receipt and debit an account  
both using the same MRL device. But in these prior art  
systems, the response of the reader is predetermined by its  
10 programming. A given reader is programmed to respond in a  
particular way to a particular MRL device.

Consider the economics of providing greater  
versatility. A manufacturer of the article to which the  
MRL device is attached would find it unprofitable to  
15 program to accommodate unique responses for unusual  
scenarios. For example a cereal manufacturer would be  
unlikely to bother drafting a unique and useful response  
for an event like scanning a box of cereal with a table saw  
reader. The number of such requests would not justify the  
20 cost of creating a unique response for such a rare event.

The prior art information retrieval processes are  
niche processes designed for a particular MRL device or  
bar-code and type of reader. However, such rare events

could comprise a large proportion of scan events, if intelligent responses were generated by the system. For example, suppose the user in the previous example wished to build a shelf unit that could support boxes of cereal? Or  
5 supposed the user was eating cereal as a snack while working in his/her tool shop? In the former case, there is intelligence in the cereal box that could be used to tailor a response, that is, that the cereal box has certain dimensions. In the latter case, there is intelligence in  
10 the type of reader, for example the indication that the user is likely in a tool shop as opposed to somewhere else. This hidden intelligence could be used to select a relevant response. In the first case, the table saw manufacturer might have sufficient demand for plans for shelving units  
15 for it to make sense to provide a number of plans. Also, a cereal manufacturer would probably have information about cereal (or other products that could be cross-sold) that is particularly relevant to users who like to eat cereal as a snack.

20 As discussed above, there are advantages to providing a high degree of versatility. The motivation for doing this is that unusual scenarios like the scanning of a cereal box with a reader built into a table-saw could be a

commonplace if useful results could be obtained. For example, users would be more likely to use a system if its results were more relevant to them, thereby increasing the probability of its use exponentially. Using hidden

5 information also permits the system to respond automatically, avoiding the need for user input (as for navigating menus), or at least reducing the need for such input. Also, suppliers of content to readers can exploit the "hidden" information in requests for information for  
10 directed marketing.

In addition to using the context to filter a large number of options down, the invention seeks also to provide an infrastructure capable of providing this kind of versatility economically. The approach is to use known  
15 components of resource retrieval technology in a novel combination for the retrieval of resources in the domain of MRL readers. At first blush, it seems strange for anyone to manufacture a table-saw reader unless an attractive use for MRL devices in connection with table-saws could be  
20 found. The obvious approach under the prior art model is to design the reader to deliver instructions from the table-saw manufacturer for various kinds of work-pieces that might be used with the table saw or for the cereal

maker to do the same. A table saw manufacturer might provide information such as the kind of blade that may be used with a piece of plastic labeled by a MRL device or instructions on how to install and adjust a Dado blade.

5 However, this monolithic model in which a manufacturer or vendor must anticipate precisely how products will be used in order to provide useful resources in response to a scan, is highly limited and inflexible. So, as in the example, the table saw reader is likely to be unable to respond with  
10 more than a generic response based solely on the MRL device of the box of cereal.

Referring to Fig. 7, a system to make the connection between resources and a reader uses components of modern information retrieval technology to provide  
15 flexibility. A reader 609 receives data from a MRL device T and transmits this data, along with an identification of a user (or user profile data from a preference data resource 611) and an identification of the reader to search engines 603 and 607. The search engine 607 is programmed  
20 to search one or more resource bases indicated symbolically at 605, for example a resource base maintained by the manufacturer of the product identified by the MRL device or the reader 609 manufacturer. It is assumed that the search

engine 607 is programmed to accept the indicated input data and that typical formatting steps are employed to formulate a query and obtain results which are the output to a formatter 613. This type of search process is essentially  
5 the same as contemplated systems in the prior art.

The search engine 603 searches the Internet 601. For example, the search engine 603 could incorporate a search engine such as Google®. The query used for searching is, preferably, generated from the contents of  
10 the MRL device T either directly or indirectly. For example, if the MRL device contains only a serial number, it may be necessary for some process (not illustrated) to look it up on a remote server, or perhaps a database in the reader 609, to determine what the MRL device is connected  
15 with. Alternatively, the MRL device may store one or more characterizations of the article to which it is connected. For example, it could contain the label "sweet breakfast cereal," and/or "Cap'n Crunch®." Once the nature of the article identified in the MRL device is determined, it can  
20 be incorporated in a search query by the search engine 603. A characterization of the reader may be done in the same way. The reader may be programmed to provide a unique

alternative characterizations) of itself for purposes of  
formulating a query for an Internet search engine. The  
characterization of the reader may also be incorporated in  
the query. The same may be done with any profile data.

5 For example, the query could contain a particular set of  
profile data that is specifically set aside for Internet  
searches. Alternatively, the profile data may be left out  
for the Internet search by the search engine 603. The  
query may employ a template, or set of templates for  
10 alternate queries, with slots for the characterization of  
the reader and slots for the characterization of the  
labeled article. For example "Use [reader] with [article]"  
or simply "[reader] AND [article]." The results retrieved  
by the search engine 603 may then be sent to the formatter  
15 613 and arranged into an output to the reader 609 via a  
user interface (UI) built into it.

Note, the term "resource base" is used here to  
identify any kind of data space that is computer-  
addressable including the World Wide Web, databases,  
20 servers such as news feeds, media feeds, with connections  
via packet and switched services such as the Internet and  
regular telephone and cellular phone services. Resources  
in the resource base may be data or process objects so that

the resources found in searching the resource space may result in the initiation of a process, such as the automatic control of a remote system, the automatic initiation or completion of a transaction such as a bank deposit, or the initiation of a dialog with a user using the reader 609. The resource base may be made and maintained by any entity and can be a conduit, such as a web content aggregator, that combines resources from several sources.

The system of Fig. 7 highlights a potential shortcoming. The Internet search engine 603 will generate a query that may be too narrow to produce meaningful results. For example, there may be few resources that contain text or metatags with Cap'n Crunch® and "table saw" or, at least, these are likely to be only a fraction of the resources that could potentially be relevant. Referring now to Fig. 8, this problem may be addressed by providing a further stage to the input-gathering process. In the present embodiment, preference data is obtained from a preference store 611, MRL data from a MRL device T, and reader data from a reader 609, as discussed relative to the Fig. 7 embodiment. The characterizing terms, however, are filtered through a term dictionary 607 before being

incorporated in a query by the Internet search engine 603.

The term dictionary 607 provides words and phrases that have some relationship to critical terms supplied by the reader 609. These relationships can be synonyms,

5 hypernyms, terms that indicate where or how a thing characterized by a search term is normally used, etc.

The need for the dictionary 607 is that the user is unable to, in the scenario of using a particular reader to scan a particular item, to specify what it is about the item or the reader that is relevant. For example, if the user was concerned about making a storage unit with the table saw and the box of cereal simply provided external dimensions for articles to be stored in it, this much would be inferred by the search process from the circumstances.

10  
15 Thus, the embodiment of Fig. 7 may be substantially improved by adding a further process to generate alternative terms that are linked in some way to the terms characterizing the reader and the article to which the MRL device is attached.

20 An example of a type of dictionary that is currently used in formulating search queries from an input search query is a thesaurus of synonyms. The present application would benefit most from a dictionary that

provides the kinds of relationships among the terms in a query that may allow a context to be derived. For example, the term "table saw" can be related to genus words (hypernyms) like "tool," or to its parts like "saw blade,"  
5 or to locations such as "wood shop" or more generically "hobby venue."

An example of a dictionary that relates terms to other terms along a variety of different dimensions is WordNet, a lexical dictionary used in the field of  
10 computational linguistics. WordNet relates words to other words that are related to a subject word along various dimensions. It provides hypernyms, antonyms, meronyms (meronym is a word that names a part of a given word),  
15 holonyms (holonym is a word that names the whole of which a given word is a part), attributes, entailments, causes, and other types of related words. Such a dictionary could be used to create alternative queries that would have a much higher likelihood of producing useful results under certain circumstances, such as the table saw/cereal box example.  
20 Thus, a dictionary that provides terms naming a place where a reader is likely located might be used. So, for example, the search process might correlate table saw with basement or workshop as the place where the table saw would normally

be located. Since the terms can, in many instances, be identified with an object very specifically, for example, the precise box of cereal including its date of manufacture, the type of paper its packaging is made of, and the expiration date stamped on the package, the related information can be very precise. Thus, a "dictionary" may be created to provide a set of additional terms that are related in various ways to terms generated directly from the context. For example, the relationships can be such as:

1. how a named object is used,
2. where a named object is used,
3. when a named object is used,
4. the language spoken in a destination city,
5. physical dimensions of an identified object,
6. other characteristics of the named object, etc.

The list is far from exhaustive, but simply intended to illustrate the idea by way of example. Instead of formulating a single query (or several based on synonyms from a thesaurus or alternative terms by stemming), significant terms in the original query may be selectively expanded by means of a specialized "dictionary."

5 The purpose of the dictionary 607 is to multiply  
the kinds of information available in a query based upon  
nouns characterizing the article to which the MRL device is  
attached, the reader, terms defining preferences, and any  
10 other data. As mentioned previously, however, a variety of  
different kinds of information can be provided at the  
outset, without requiring a separate dictionary. For  
example, the MRL device T could point to a particular  
article by means of a data resource, say a database  
15 maintained by the manufacturer of an article to which the  
MRL device was attached. That database may contain a set  
of alternate terms that serve to identify the object, the  
places it is normally used, ways it may be used, its  
physical dimensions, etc. The MRL device T could contain  
20 these alternate terms at the outset. But such an  
arrangement presupposes that the entity that provides  
information about the article has chosen to provide all the  
information that could be relevant about the article.  
Also, preparing and maintaining the currency of this kind  
of data can be onerous unless there is a significant  
incentive for the entity with access to the data. In some  
cases this is virtually impossible (for example, the  
location of a portable reader at the time of the scan) and

in practice, it is likely to be very difficult simply because (e.g., the delicatessen that prepared the potato salad) not all parties involved will have the resources to provide all the information required. The alternative is  
5 for the system to have a generic dictionary that it can use to expand any terms, and filter the results based on the quality of the matches obtained.

For an example of how the term dictionary can help provide a meaningful context, if the reader 609 is  
10 associated with a cement truck and the query identifies the reader as a cement truck, the term dictionary 607 may provide a hypernym for the cement truck, returning "vehicle" or its standardized equivalent. In a query in which a Coke® was scanned by a cement truck reader 609, the  
15 resource space is more likely to be populated with responses pertaining to Coke® and vehicles than it is to contain cereal boxes and cement trucks. For example, the query might generate a response indicating where the product in the cereal box can be purchased. Just to  
20 complete the example, one can imagine a worker wishing to purchase a case of Coca Cola® on his way back to a station and it being convenient for him/her to stop while in a cement truck.

As in the system of Fig. 7, the outputs of both search engines 603 and 607 are supplied to a common formatter for application to a UI 615. Note that the UI 615 can be a local process on the reader 609 or a remote process on a server as may be the formatter 613. Note that the term dictionary 607 may be multiple separate processes rather than just one. These may be local (incorporated in the reader 609) or remote (addressable by the reader 609). Preferably, one or more generic dictionaries may be maintained by one or more service providers.

The input terms may be descriptors chosen by authors and incorporated in MRL devices or a database correlating the MRL device identifier with the descriptors. In situations where these descriptors have not been expanded in advance, the generic dictionary process 607 handles it. An example of its use is the case of the delicatessen preparing a potato salad. The only information about the article is the terms "potato salad," the date it was prepared, the date the potatoes were boiled, the ingredients list, the weighed size of the original quantity sold, and an identification of the vendor who prepared and sold it. In this case, the precise size of the container, a location where it is normally found

(e.g., in a refrigerator or at a dining facility) and other precise information about the article, the reader, or other descriptors that might appear in a query are not available. But in such cases, for such terms, a dictionary built  
5 around the generally-recognized meanings of words and other terms, may be employed to expand the search terms.

The above example of a cement truck and a case of Coke® may seem far-fetched, but one of the goals of the inventive system is to provide value in rare circumstances  
10 for which it might otherwise be too expensive to create links to particular resources. As discussed, such rare circumstances may account for a significant percentage of the opportunities for using the system. There is a synergistic benefit to providing meaningful responses to  
15 unusual requests. It means that users can anticipate that the system is useful most of the time, even when the circumstances are not paradigmatic. The more often the system can be used, the more likely the user will turn to it when more common circumstances permit. It may also  
20 prove to be fun for a user to discover some unimagined connection between where s/he is currently, what s/he is doing and some object identified by a MRL device. This can create powerful marketing opportunities.

One way the search process can be improved is to insure that queries and the indices employed by the search engines 603 and 607 use the canonical form of query terms. The canonical forms may include stemming and replacement, if necessary, by one chosen canonical stem term to replace a variety of synonyms of the stem. This would be done with query terms and descriptive text (including metatags) in the resources. This may not be necessary in some instances. For example, a reader may always characterize itself using standard terms and variants. The advantage of allowing resources to use terms other than standardized terms is that it allows them to be generated more easily and by persons with less technical sophistication. Creators of resources can simply borrow descriptive language from another source or draft it without being concerned with conforming to a standard vocabulary.

Referring now to Fig. 9, the UI 615 may display a result such as indicated in an illustration of a display 642. Two display regions are shown: a first region 640 for displaying results from the search by the search engine 607 and a second region 644 displaying results from the Internet search by search engine 603. The first region 640 indicates instructions at the beginning of an automatic

microwave oven programming process. The reader 609 display  
642, which could be built into the microwave oven, provides  
a control 643 to begin the cooking process and another  
control 643 to allow the user to opt-out of proceeding  
5 ahead with cooking to go to a menu providing further  
options. The regular search engine 607 also generated a  
result for advertising a sale at BuySmart and for cross-  
selling another product, namely frozen peas with a coupon  
incentive which the user may select to receive by email or  
10 some other means. The second region 644 contains high  
priority region 646 and a low priority region 648. Search  
hits that are deemed high priority, for example by the  
confidence level of the hit, such as indicated by most  
Internet search engines and used for ranking results (e.g.,  
15 by TF\*IDF) are displayed in the high priority region 646  
and expanded. The results with lower ranking are displayed  
in the low priority region. Other criteria may be used to  
rank the results, such as the presence of an indicator, in  
the resource, to a health warning.

20 Referring now to Fig. 10, the most sophisticated  
search engine technology currently available employs  
natural language (NL) processing to parse search queries  
generated by users. For example, a user can formulate a

search by typing in a question in the AskJeeves® search engine. The sentence typed in by the user is parsed to identify the most important terms. Noun-phrase identification, stemming, conversion to canonical terms, etc. may be performed. More sophisticated techniques may allow for greater semantic discrimination in the search query. In the current system, these techniques may not be required in the front-end process of creating a query vector, since the MRL device, reader, and user preference model may be such that the respective terms they contribute are unambiguously tagged to indicate the meanings of the terms they contribute. So, for example, the reader can identify itself as a reader mounted on a table saw and the MRL as an identifier of a particular brand and type of cereal made on a date-certain at specified place, etc. Note that, as discussed elsewhere, however, this information may simply be correlated to a unique identifier stored in the MRL device. Thus, there is no need for information extraction using NL techniques for determining the semantic structure of the data incorporated in the query. However, such NL techniques can be very useful for determining the semantic structures of unstructured response databases, such as the WWW.

Relatively unstructured response databases are much easier to create and grow than highly structured ones. This may be key to the development of rich data resources that will contribute to the vision of a future in which users can scan just about anything anywhere to obtain responses they truly value. In fact, contributions can come from the users themselves, as users contribute to the WWW. Since, in many instances, a scan event may be very predictable, for example scanning the MRL device of a frozen dinner with a microwave oven's scanner, it is desirable for some responses, in such circumstances, to be retrieved directly without resort to the filtering of large quantities of unstructured resources. Thus, it is desirable for structured databases to exist alongside unstructured ones, or for the search mechanisms used for searching unstructured resources to produce predicted results. For example, a manufacturer could plant unique metadata in its web sites that correlates with certain MRL and reader data to guarantee the search process retrieves the desired resource with a high confidence level (i.e., desired response is weighted highly relative to all others and so is guaranteed to be in the short list of returned results).

5

10

15

20

Bayesian network fashion). An input vector matching any of these templates perfectly would cause the information provider server to generate a very high goodness of fit ("confidence") indication for one of the responses and a low one for the others. A template matching only one component of the input vector would produce a lower rating. If no other match competed with this lower rating, then the corresponding response might be generated by the server. The latter situation would result in multiple good fits and might require a request for further information to make the correct choice clearer.

The above examples are trivial. In large databases, the fit between input vectors and responses may not be provided by a weighted factor template as in a Bayesian network (or neural network or other machine-intelligence technique) because they are so time-consuming to program (train). A more practical way to make a response database is to draw on technology being used in search engine and question-answering systems where the criteria for selection and the contents of the responses are natural language descriptors. In question-answering systems (or frequently asked question; FAQ selectors), a natural language (NL) question is parsed to identify the

most significant terms. These are then compared to  
templates in the FAQ database. The templates are derived  
from the questions to which the corresponding answers are  
responses. An extension of this technology would be for  
5 the templates to be ordered sets, each element  
corresponding to a particular type of input. For example,  
a first element could correspond to "whom," indicating one  
or more identifiers relating to the type of person making a  
request and the values indicating male adult, female child,  
10 ethnicity, age, etc. Other elements might correspond to  
the location of the requester, for example a value could  
indicate "moving in a vehicle," "at home," "at work," etc.  
Other element(s) could relate to the type of reader being  
used such as "microwave oven," "table-saw," or "kiosk."  
15 The input vector may be ordered in the same way. One way  
of expressing the ordering is by data-tagging, for example  
using XML.

In practice, processes for matching inputs to  
responses using either-or comparisons between the  
20 components of input and template vectors could be used to  
correlate responses quite effectively in a practical  
system, even though the number of responses and input  
combinations may be high. Usually in programming such a

system, many vector components would be ignored, reducing the size of the input vector space. Also, the provider may classify the kinds of requests to be received, and provide some default response when no input vector matches a response template. For example, assume the information provider is a manufacturer who provides information to support purchasers of its products. The manufacturer may match each request identifying one of its products to a corresponding set of responses. Each of the responses may be created for dealing with a particular reader that was expected to be used for scanning the attached MRL device. For instance, for frozen dinners, the reader component of the input templates might include various models of microwave ovens, regular ovens, and hand-held portable readers. When the product fails to match one of the anticipated devices associated with the reader, the server programming might generate a default response.

In Fig. 10, a configuration that uses a dictionary on the resource side of the system is illustrated. A MRL device 400 is read by a reader 405. The reader 405 applies relevant characterization terms resulting therefrom to a dictionary process 410. The dictionary process 410 generates alternate terms as

discussed above and applies these to a resource search  
engine process 425. The resource search engine process may  
optionally receive general data 415 and profile data 430,  
such as preferences and characteristics relating to the  
5 user. The resource search engine process 425 then  
generates a set of alternative search queries with which it  
searches an index 435. The index is generally regarded as  
a data object part of the search engine process, but here  
it is illustrated separately to facilitate discussion of  
10 the embodiment.

On the resource side of the system, the index is  
populated by an indexing engine 445, which filters resource  
templates 460 through a natural language parser 450. The  
resource templates 460 are descriptors of the various  
15 resources available in a resource base 455. In databases,  
these descriptors can be the contents of the database  
itself, or separate fields used for searching, like tags  
(e.g., XML) used by some resource bases like WWW sites  
(e.g., metatags). Here, the resource templates 460 contain  
20 the terms that characterize the records in the resource  
base 455. The templates are not precisely configured as in  
a normal database. In fact, the resource templates 460 may  
simply be text abstracts describing the contents of the

resource. Alternatively, the templates may be subsumed within the records of the resource base 455. The use of natural language abstracts as templates (or template precursors if the abstracts are parsed and then structured as templates) may facilitate the contribution of new templates by users. This idea is discussed elsewhere in the present specification. See, for example, the discussion attending Fig. 21.

Referring now to Fig. 11, in another embodiment, a user state 235 and context of use is derived from a scan event. The user state includes all available information from the reader, which may be a portable device with a personal information manager, cellular phone, GPS appliance with a mapping database storing the whereabouts of the user over time, etc. The reader (not illustrated in Fig. 11) may be networked to other devices so that the reader may actually be able to determine its location. For example, if a portable reader is able to join a piconet temporarily and ascertain that it was brought into a grocery store, the portable reader could retain an indicator of that event for use in determining the user's current state. Similarly, information about who the user has been in contact with may be available in a device either combined with the reader or

connectable to the reader. All user state information that  
is relevant to a scan event is applied to an Internet  
search process 233. Permanent preference data may be  
stored in a preference data store 237 and selected portions  
5 of its data applied to the Internet search process 233 to  
refine it. The same data is selectively applied to a  
response database search 240. A response resource base 238  
is different from sites on the Internet in that it is  
structured for servicing MRL readers. In the present  
10 embodiment, templates 241 of the response resource base 238  
correspond to templates 460 in Fig. 10. These contain  
ordinary language terms that have been previously parsed by  
a NL parser and built into the templates corresponding to  
each record. The templates 241 may thus be ordered sets of  
15 data with fields that indicate key features of the  
responses 239. In other respects the resource base 238 is  
searched as discussed above.

Another feature of the present embodiment is that  
a dictionary, incorporated in a term expander process 245,  
20 is only applied to expand query terms when the response  
database search process 240 has determined that the  
confidence levels of the results are all poor. This  
preserves computational resources by not doing searches

when direct use of the original search terms may produce a result with high confidence. The Internet search process 233 and the response database search process 240 both generate respective sets of responses 234 and 236, each  
5 with a corresponding confidence level. In the present embodiment, these are applied to a selector/formatter process 250 to generate a final selected set 249 which may be displayed by a UI element 255.

10 The templates 241 may be structured in any desired fashion to reduce the accuracy of matches to queries and increase the searching efficiency. Also, the embodiment of Fig. 11 may be modified to incorporate a term expander 245 in the Internet search process 233.

15 Preference data store 237, (as well as profile 430, Fig. 8, preference database 611, Fig. 7, and similar components in other figures) may contain data obtained by various means. A first type of device for building a preference database is a passive one from the standpoint of the user. The user merely makes choices (e.g., menu choice  
20 in a browser built into a reader) in the normal fashion and the system gradually builds a personal preference database by extracting a model of the user's behavior from the choices. It then uses the model to make predictions about

what the user would prefer to watch in the future or draws inferences to classify the user (e.g, a baseball enthusiast or an opera lover). This extraction process can follow simple algorithms, such as identifying apparent favorites  
5 by detecting repeated requests for the same item, or it can be a sophisticated machine-learning process such as a decision-tree technique with a large number of inputs (degrees of freedom). Such models, generally speaking, look for patterns in the user's interaction behavior (i.e.,  
10 interaction with a UI for making selections).

One straightforward and fairly robust technique for extracting useful information from the user's pattern of behavior is to generate a table of feature-value counts. An example of a feature is the "time of day" and a  
15 corresponding value could be "morning." When a choice is made, the count of the feature-values characterizing that choice are incremented. Usually, a given choice will have many feature-values. A set of negative choices may also be generated by selecting a subset of shows at the same time  
20 from which the choice was discriminated. Their respective feature-value counts will be decremented. This data is sent to a Bayesian predictor which uses the counts as weights to feature-counts characterizing candidates to

predict the probability that a candidate will be preferred  
by a user. This type of profiling mechanism is described  
in US Patent Application Ser. No. 09/498,271, filed  
2/4/2000 for BAYESIAN TV SHOW RECOMMENDER. A rule-based  
5 recommender in this same class of systems that build  
profiles passively from observations of user behavior is  
also described in the PCT application, WO 99/01984  
published 1/14/99 for INTELLIGENT ELECTRONIC PROGRAM GUIDE.

10 A second type of device is more active. It  
permits the user to specify likes or dislikes by grading  
features. These can be scoring feature-value pairs (a  
weight for the feature plus a value; e.g., weight =  
importance of feature and value the preferred or disfavored  
value) or some other rule-specification. For example, the  
15 user can indicate, through a UI, that the user prefers  
dramas and action movies, and that s/he does not like  
cooking. These criteria can then be applied to predict  
which from among a set of alternatives would be useful to  
the user.

20 As an example of the second type of system, one  
EP application (EP 0854645A2) describes a system that  
enables a user to enter generic preferences such as a  
preferred program category, for example, sitcom, dramatic

series, old movies, etc. The application also describes preference templates in which preference profiles can be selected, for example, one for children aged 10-12, another for teenage girls, another for airplane hobbyists, etc.

5           A third type of system allows users to rank resources in some fashion. For example, currently, a digital video recorder called TIVO® permits users to give a program up to three thumbs up or up to three thumbs down. This information is similar in some ways to the first type  
10 of system, except that it permits a finer degree of resolution to the weighting given to the feature-value pairs that can be achieved and the expression of user taste in this context is more explicit. So, for example, a UI used in the present invention may have an OK button to  
15 acknowledge and close a current dialog box or display element. Alongside the OK button, the UI could show a NOT OK button to allow the user to close the dialog, but indicate that the response was not useful.

20           A PCT application (WO 97/4924 entitled System and Method for Using Television Schedule Information) is an example of the third type. It describes a system in which a user can navigate through an electronic program guide displayed in the common grid fashion and select various

programs. At each point, he may be doing any of various described tasks, including, selecting a program for recording or viewing, scheduling a reminder to watch a program, and selecting a program to designate as a favorite. Designating a program as a favorite is for the purpose, presumably, to implement a fixed rule such as: "Always display the option of watching this show" or to implement a recurring reminder. The purpose of designating favorites is not clearly described in the application.

However, more importantly, for purposes of creating a preference database, when the user selects a program to designate as a favorite, she/he may be provided with the option of indicating the reason it is a favorite. The reason is indicated in the same fashion as other explicit criteria: by defining generic preferences. The only difference between this type of entry and that of other systems that rely on explicit criteria, is that when the criteria are entered. The present system may build profile data using any of the techniques described above.

Profile data may be used to modify queries as discussed above. However, under certain circumstances, the profile data may include a stored correlation between a type of scan event and a resource to be used. For example,

a user might define a response for programming a microwave oven to thaw ice cream. The use of the profile and the search for responses should give a high weight to resources created by the user for use in clearly defined

5 circumstances. Thus, the profile may contain its own list of resources and templates that are used to match a query in preference to a search of an external resource base.

Referring to Fig. 12, a modification of the process of Fig. 6A allows a user to receive information through a fixed 120 or portable reader 100 and, in case the user chooses not to receive a response at that time or the portable reader 100 is unable to connect to the server 140, the response is delayed and continued later. Assume the user scans the MRL device T causing the reader 100/120 to  
10 acquire data from the MRL device T in step S10. In step S12, the reader 100/120 determines if it is able to connect with the network/Internet 130. If the reader 100/120 is connected, the interaction may be initiated between the reader 100/120 and the LAN server 140 or Network server 140  
15 beginning with the transmission of data to the network server 140 at step S16. For example, the data transmitted may include data from the MRL device T plus other information, the other information including, for example,

the identity of the user and/or certain profile data  
characterizing the user. Included with the information  
from the MRL device T may be a network address to which the  
reader 100/120 may connect to complete the information  
5 exchange. The interaction is continued as defined by the  
interaction process running on the server 140 at step S20.  
The data exchanged in the interaction may include data  
responsive to the acquired data, further user input, and/or  
data stored on the network server 140. Generally, it is  
10 contemplated that the interaction would be conducted in  
accord with, and by means of, a client-server process, for  
example using HDML (handheld device markup language), a  
markup language for small wireless devices or HTML  
(hypertext markup language).

15 When, in step S12, it is determined that the  
reader 100/120 cannot link to the server 140/150, the  
reader 100/120 may store the acquired data in its memory M  
at step S14. Optionally, at step S18, the reader 100 may  
indicate the fact that the data may be stored locally and  
20 request acknowledgement in step S22. The acknowledgement  
may include giving the user the option of erasing the data  
stored in step S20.

In step S24, the status of the reader 100 may be ascertained. If it is connected and contains unprocessed stored data, having come through steps S14, S18, and S22, control passes to step S28 where the interaction or other  
5 interaction process that did not occur previously is initiated. Among the data transmitted in step S50 to the network server 140/150 may be the time since the HMDR device T was scanned. From this, the interaction process may determine whether it makes sense to direct the user to  
10 a sale within the store (if it has been only a short time since the scan). Again the interaction process may provide for alternate routing of information. For example, the user could request that relevant messages, coupons, etc. be sent by email, if possible.

15 The process of Fig. 12 provides for a stationary loop process when the reader 100/120 has nothing to do as indicated at step S24 and to return to step S10 when a scan is initiated.

Referring now to Fig. 13, in an example sequence  
20 that may occur according to the process of Fig. 12, the reader 100/120 acquires data from the MRL device T at step S40 and transmits it to an information supplier who has programmed the network server 140 at step S42. A message

is generated by a software process (interaction process) running on the network server 140 which results in the reception of a message by the reader 100/120 at S46. The message is then output by the reader 100/120 at S48.

5           The data acquired by the reader 100/120 may include simply a unique identifier of the device or it could contain standardized symbols indicating product code, serial number, retailer to which the product was shipped, etc. The latter data, as indicated by brackets, however, 10 may be derived from a unique identifier if the latter are correlated in a database of the information supplier. The data sent to the information supplier may include the date of scan, the time of scan, the scanner's (or person's) identity, and other information not derived from the MRL 15 device T but available. The scanner identity may be unique or a code for a profile classification or may point to a particular profile without identifying the scanner explicitly. Again, the profile data could also be sent by the reader 100/120.

20           Referring now to Fig. 14, in another example sequence, data is acquired at S80 and stored at S82. At a later time, the reader 100/120 becomes connected and, in response to this event, transmits the data acquired at S80

to an information supplier at S84. The information  
supplier then sends a responsive message to the reader  
100/120 at S86. The reader 100/120 then stores the  
responsive message at S88. Later, at the occurrence of  
5 some event that corresponds to a good time for output, the  
good time event being determined by some process such as a  
direct request by a user indicated at the reader 100/120,  
the stored message is output at S90. The reader may be  
programmed to output the message automatically when the  
10 reader 100/120 is able to establish connection (i.e., the  
reader 100/120 determining that it is connected).

Referring now to Fig. 15, yet another sequence  
begins with the acquisition of MRL device T data at S30.  
The data is stored at S32. At some later time when the  
15 reader 100/120 is connected, the stored data is sent to the  
information supplier at S34. The information supplier  
sends a message which is received at S36 and sent to the  
reader 100/120. At some time later upon an event  
indicating it is a good time for the delayed interaction,  
20 the message is output to invite the user to begin  
interacting with the information supplier at step S38. The  
message may be a simple invitation or may indicate some  
feedback based on the data sent at S34, such as a menu of

options defined at the beginning of the interaction process.

Referring to Fig. 16, yet another sequence begins with the acquisition of MRL device T data at S70. The data is stored at S72 on the reader 100/120. Then, when the reader 100/120 is connected, the reader 100/120 connects to the network server 140 and transmits the stored data at S74. At S76, the user is prompted to accept a message from the network server 140, and upon acceptance, the message is delivered at S78 concurrently or at a later time. Several illustrative examples follow.

The dialog may take place at a later session in response to an email as follows. The user indicates at S76 that he/she wants to participate in the interaction at a later time to be initiated by the user by selecting an HTML link in an email message. (Obviously, the invitation need not be so complicated, for example, the user may be presented at 40 with a selection labeled: "Send email alert to learn about <product> later.")

The dialog may take place later through a targeted TV advertisement or interactive TV session as follows. (For purposes of the present discussion, these may be essentially the same as a terminal connected to the

Internet, a television and set-top box being essentially  
its equivalent.) The user selects an option for TV  
delivery and the interaction is scheduled to take place at  
time when the user's TV is active (or at some time selected  
5 by the user). Other alternatives corresponding to S78  
include the user indicating a desire for a telephone or  
personal sales call, or regular postal delivery of  
information.

10 Note that the process at S78 may occur on the  
portable terminal, on a stationary appliance, such as one  
located at a retail premise, or on any other device.  
Referring to Fig. 17, the determination of a good time for  
beginning or continuing a delayed interaction, information  
delivery, or transaction may be determined by a fixed time  
15 delay S301, an event indicating the user is at a particular  
location or involved in a predetermined activity S302, the  
synchronization of a portable reader with a stationary  
terminal S303, or simply a random time S304. When any of  
these events S301, S302, S303, S304 occurs, a request for  
20 service is initiated at step S310 and the interaction  
process is continued or begun. For example, the user may  
access an Internet portal and receive the message in  
response to logging in or the user's cookie correlated with

the identity data transmitted at S74. Stored data  
corresponding to a delayed interaction may be given an  
expiration time and date and caused to expire after the  
passage of that time S305. In that case, an alternative  
5 process can be performed S305 such as giving the user the  
option of delaying the interaction further, emailing a  
message, etc. The data and the incipient interaction may  
be purged by either the reader 100/120 or the network  
server 140.

10           Whereas in the above embodiments, the invention  
was described in terms of information exchange, it is  
contemplated that these exchanges could trigger actions as  
well. For example, one result of the interaction process  
15 could be the online purchase of a product. Also, the  
interaction need not occur on the reader 100/120 that sent  
the data. The interaction may take place through a  
connection to the information supplier provided by a  
different appliance such as one of the appliances 170-190.  
20 One way to initiate the interaction through the alternate  
appliances is by scanning the MRL device T with a scanner  
of the appliance. Another may be by synchronizing the  
reader 100 with the appliance where, for example, the

message received at 34 is conveyed to the appliance along with other data required to complete the interaction, if necessary according to the interaction process.

Referring to Fig. 18, putting a few of the above features into an embodiment, scan and other data is acquired in step S110. The best matches in one or more resource bases are determined in step S115. Then, it is determined in step S120 whether the confidence level of one or more results is high. If none of the results has a high confidence level, in step S140, new terms are generated using an appropriate technique, such as a related terms dictionary as described above or by disambiguating the search query by seeking new information from the user. In this case, the discriminant identification in the search results, discussed below in connection with Fig. 24, may be used to obtain additional feedback from the user. Then a new search is done in step S145 and the results checked for high confidence in step S150 as in step S120. If the results show no high confidence results once again, a search for a high confidence match is done by replacing terms in the query with other terms that are not necessarily related to the replaced term. This may be described as a hunt for a remote match S156. For example,

if the cereal were scanned with a table saw, the "table  
saw" term might be replaced with a number of alternatives  
more closely related to other search terms such as "cereal"  
even though the replacement terms may be remote from the  
original term. Such terms might produce a high confidence  
5 response, such as cupboard would produce in combination  
with cereal. The search with one or more replacement  
terms, if successful S157, causes the reader to steer the  
user to the article identified by the replacement term in  
10 step S159. If the search is unsuccessful, a generic  
response S158 may be generated. At all or any points in  
the procedure flow of Fig. 18, the user may be given the  
option to opt out of the search for a response to permit  
the user to create a new response and response template for  
15 future use in step S155. For example, in step S155, the  
user could program a microwave to heat something for which  
the reader system did not have a particular response in its  
resource base. Note that the above procedure may also be  
modified so that a generic response S158 is output along  
20 with a message suggesting a different device as in step  
S159 or to allow the user the opportunity to go from step  
S159 to step S158 if the user desires, by generating  
appropriate UI controls.

If in either of steps S120 and S150, the confidence level of one or more results is determined to be high, the system determines, in step S125, if there is a single response with a high confidence level, or more than  
5 one. If there is more than one, then the choices are presented to the user in step S130 and the control flow passes to step S160 of Fig. 19. If there is only one choice, then control flow passes directly to step S160 of Fig. 19.

10 In step S160, the user's preference with regard to how a single dominant result should be handled is determined. Some users may prefer to have a system automatically take action, for example to program the microwave oven, to save time. Other users, being less  
15 concerned about efficiency, may prefer to control the process all the time. Users may change this option, depending on where they are. For example, if the user is shopping, the user may not want information delivered immediately, but prefer to be given the option of routing,  
20 for example by email or some other means, for later review or handling. If, on querying a user profile data store, it is determined that the direct response is preferred, an appropriate action defined by the resource is implemented

in step S145. This may be simply the immediate delivery of information to a reader display.

Two other possibilities for handling resources are defined in the embodiment of Fig. 19 and dictated by the user's preference (or possibly some other means, such as the type of reader, the time of day, the location of the reader, the type of resource being delivered, etc.). One is that some resources, because they satisfy a priority exception list, should be directly implemented. For example, the user may be keenly interested in certain results, such as a health related warning or news item or weather warning. In such cases, the user may want the resource to be delivered or implemented. In step S170, this kind of exception is implemented. If the resource corresponds to a high priority resource or other type of exception, the resource is delivered or implemented in step S165. Otherwise, in step S180, the user is given an option of deferring, ignoring, or delivering or implementing the resource retrieved. This last step S180 involves getting input from the user. If the user chooses to ignore the resource S185, the process terminates. If the user chooses to deliver or implement the resource, the action is taken in step S165. If the user chooses to defer the delivery or

implementation of the resource S175, the offline procedure of previous embodiments may be implemented causing a delay for the arrival of a good time S190 until either the action is completed S165 or some event such as the expiration of  
5 the time to live timer, whereupon the resource retrieval and delivery process thread is terminated S195.

Referring to Fig. 20, a process for generating messages on the UI of a reader in the absence of a scanning event begins with detection of the presence of a user in  
10 step S405. Alternatively, the loop of Fig. 20 can be run continuously or on an intermittent schedule or scheduled in some other way. In step S407, a resource is automatically requested by the reader and a response received. The request may be generated from user preference data. In  
15 step S410, the resource received is compared to the user preference data and rejected, in which case control passes to step S405 or accepted in whole or in part, in which case it is delivered in step S415 and control returns to step S405. Note that delivery of the resource may involve the  
20 initiation of the interaction or some automatic process or simply the delivery of information, like an advertisement.

Referring to Fig. 21, a procedure by which new resources and templates may be generated begins in step

S430 with the presentation of one or more candidate  
resources for the user to select. For example, if the user  
scans an ice cream MRL device with a microwave oven reader,  
the server might come up with irrelevant (to the user)  
5 responses or none at all. For example, see step S156 in  
Fig. 18. Then the present procedure might be invoked to  
give the user an opportunity to define programming  
instructions for the microwave oven. For example, the user  
may define instructions for defrosting the ice cream (e.g.,  
10 50% power level and 60 seconds time). The next time the  
user uses the microwave oven reader to scan an ice cream  
MRL device, the server could respond immediately with  
instructions for programming the microwave oven. In  
addition, the server could make the instructions entered by  
15 one user available to other users, either optionally or  
automatically. In step S433 the user either accepts one of  
the alternatives, in which case the accepted resource is  
implemented and stored as a preferred resource for the  
given circumstances S460, or rejects them all. Here the  
20 user is giving feedback that may be used to augment the  
profile data as discussed above. In step S435 a UI is  
generated to permit the user to indicate a type of resource  
and accept input defining it. In step S440, a UI is

generated to permit the user to specify any required  
details or parameters for the resource. For example, if  
the resource is a microwave oven program, the user could  
specify time, power level, etc. In step S445, the entered  
5 data is stored as a new resource and template. In step  
S450, the profile data store is updated with the new  
resource and template.

10 In step S455, the resource and template are  
stored in an external provisional resource base to permit  
other users to use it. The provisional resource base may  
be handled differently from a standard one to avoid  
deliberate or accidental contamination of a widely used  
resource base with useless or dangerous resources. Thus, a  
separate resource base may be made available for  
15 provisional resources and responses to the resources  
gathered by designated subscribers (as indicated in the  
user preference profile) before an administrator determines  
what to do with them.

20 Referring to Fig. 22, a procedure for providing  
various features using a ticket stub, coupon, receipt, or  
other paper document having a MRL device attached. As  
mentioned with reference to Figs. 3 and 4, a ticket stub or  
other document may have a MRL device affixed to it. These

documents or coupons may provide a valuable marketing device, for example. A user seeing a movie may scan his/her ticket stub at a kiosk located at the movie theater and rate the movie s/he just saw, purchase goods related to the movie, and do other things. While it has been proposed that bar-codes be used on a ticket stub to connect users to web sites for purchase of goods, this degree of automation merely avoids the need for the user to enter a web address. The present idea is to make the purchase or entry of information into a preference database very easy and quick. There is a much greater likelihood of a sale when a user is provided an opportunity to buy a movie soundtrack just as the user leaves the movie with the music still fresh in his/her mind. The smaller the number of steps involved, the more likely a sale will be completed. In an embodiment of the invention, a MRL device is attached to a ticket stub. The device may contain a resource address at which the movie soundtrack can be purchased. Moreover, the device contains sufficient data density to correlate or store account, authorization, shipping, and authentication information to allow the purchase to be completed without any prompting from the user aside from the selection and confirmation of an item to be purchased. If a theatergoer

purchases tickets using a credit card, the account can be linked temporarily to data on the MRL device on the ticket stub. This data can further link an order process to preference information contained in the user-profile

5 database and the purchase used to augment that database.

To protect the user's account, the connection between the user's credit account and the ticket data may be given a predefined expiration period, say 2 hours after the movie or other event is over. As an inducement for the user to

10 purchase at the theater, the user can be given a discount incentive such as lower price on his/her next ticket purchase, discounted price for the goods ordered, or a free gift. Precisely the same functionality can be provided through a home computer connected to the Internet or a  
15 portable terminal rather than a kiosk terminal.

The procedure begins with a registration step S468 in which a user may obtain the document having the MRL device. The registration process may include obtaining account, authorization, and/or authentication information  
20 from the user, an external source such as an e-wallet, ATM network or subscriber network, or other resource. An identifier in the MRL attached to the document is then associated with the account and the necessary data for

completing a transaction in step S470. Note that in steps  
S468 and S470, the account may not involve money or credit  
at all, but may merely be an account for storing personal  
information such as preferences regarding a subject, such  
5 as movies. For example, a user could subscribe to a  
service, offered by an entertainment service, which allowed  
a user to open a private account for storing his/her  
preferences and using these preferences for various  
services in return for the user's authorization to use the  
10 data for marketing purposes. For example, the user could  
rank movies as the user leaves them. Later, after ranking  
multiple movies, the user could receive recommendations by  
email. The user's preferences could be combined with those  
of friends to generate recommendations for parties of two  
15 or more friends to see together.

In step S475, the user scans his document at a  
terminal, for example a kiosk at an entertainment venue.  
In step S480, the user is prompted for input, such as a  
selection of a product for purchase, an evaluation of an  
20 event just enjoyed, etc. The user's authorization  
information is processed by a server in step S485 and a  
response generated which may include the invitation for  
additional requests, confirmation of sale, etc. Further

transactions may be invoked and appropriate UI elements  
generated in step S40. In step S480, preferably an  
authentication step is involved to insure that a lost  
document is not used by a finder. The association in step  
5 S470 may be given a time to live (TTL) so that after the  
expiration of some predefined interval of time, the  
document and MRL device can no longer be used. By forming  
an association between the user's account and the MRL  
device's unique code, purchases and other authorization-  
10 requiring transactions can be completed quickly. The  
registration process in step S468 is analogous to the  
creation of a temporary credit card in the MRL device. As  
mentioned, however, it is preferable under most  
circumstances to attach an authentication requirement such  
15 as biometric or entry of a personal identification number  
(PIN) or symbol.

The registration process that associates an  
account with a ticket MRL may be done at a residence before  
going to the entertainment venue over the Internet.

20 Currently, there are proposals for systems in which a user  
can purchase a ticket and print it, with a bar-code, on a  
printer at home. The ticket is then scanned at the theater  
to authorize the user. This same thing could be done with

a MRL device. The user stores an association between an account and a MRL ("blanks" may be distributed free or for a nominal fee) by scanning the MRL at home and performing a secure transaction. The association with the account that permits the ticket to be used for purchases may impose a spending limit. A parent could prepare and give a ticket to a child that permits the child to attend the movie and make limited purchases. For example, the child could buy a recording or treats at the theater using the MRL as a temporary expense-limited charge device.

Referring to Fig. 23, a simple process for receiving recommendations in response to identification of the user, is illustrated. For example, at a movie theater or other entertainment venue or a web site, a user can obtain recommendations by entering an identifier (and authentication data as required) at step S491. In step S493, the user uses a control to generate a request for a recommendation, for example one relating to a specific category. In step S495, a server process generates a recommendation and stores preference data in a profile base for use in refining recommendations, cross-selling, etc. In step S497, the terminal displays the resulting recommendations, receives further input, etc. Note, the

above process may relate to restaurants, entertainment, or any kind of article or service for which many choices are available.

Referring to Fig. 24, a procedure for refining  
5 search results that identifies discriminants in the search results, if the number retrieved is very large, is illustrated. The search engine process may look for discriminants in the set of records returned and, instead of simply listing the results returned, offer the user a  
10 list of discriminants from which to select. The discriminant may be, for example, an important term that appears in a small percentage of the retrieved results, but is conspicuously absent from the others. It may identify a number of such discriminants and offer all of them to the  
15 user to select from.

The identification of discriminants is a well-developed technology in itself. A very simple approach is to generate a histogram that indicates the terms that appear most often in the returned records and to allow the  
20 user to select from among the terms with the highest frequency. Another is to look for common incidences of words not specified in the query but which appear in association with words that were specified in the query

under the assumption that the former modify the latter when they appear in mutual proximity. These former terms would be presented as options from which to select. The generation of the statistics needed to identify these

5 discriminants is straightforward from the processes employed by search engines. Search engines generate or use index files that permit the ready generation of such statistics.

The discriminants can be derived by various means.

10 For example, using the returned selection set, a histogram indicating the frequency of each term in the returned set of records can be generated. Those terms with the highest hit counts may be displayed and the user permitted to select one or more. Suppose for example that the query

15 contains the Boolean: "dog" and "fur or hair" and "curly or wavy" and the goal is to find information about a particular breed. In the example, the records returned by the search include information about various breeds, most of them focussing on particular breeds. The terms with the

20 highest frequency of hits may provide some information that can be used, if indicated by the user, to tell the search engine that certain classes of records are not desired and certain classes are desired. So, for example, common

descriptors may be returned such as "small," "large,"  
"thin," and "heavy." The user can select from among these  
to help reduce the selected records to a number that can be  
conveniently browsed or produce a desired hit. To augment  
5 this process, the UI may display the number of hits in the  
original set, the number that would result from the  
combination of any of the proposed discriminants with the  
original query, and the effect of combinations as a new  
query is generated using the discriminant terms. For an  
10 example of the latter, suppose the query contains "thin and  
small." The display could show the effect as each term is  
added. This is similar to the way Folio Bound Views® by  
Folio Corporation works where, as a search query is  
entered, the number of returned results is continuously  
15 updated.

A problem with such a simple discriminant is that  
such terms may simply tag along with the terms in the  
original search query. In other words, they may be common  
to most of the returned results and therefore act as poor  
20 discriminants among results. What is more desirable are  
discriminants that have a high probability of dividing the  
returned records by a large proportion. One way to  
identify better discriminants is to look for common

instances of words that are not included in the original query but which appear in association with those in the original query inferring that there is meaning in the association. The association may be inferred by mutual  
5 proximity of the terms, for example, or grammatical parsing (e.g., identifying adjectives that modify the search query term), etc. Those candidate discriminants that appear with the highest frequency could then be presented to the user and the user permitted to select from among them.

10 A refinement to the two previous approaches is to select discriminants based on the ability of each to divide the returned set into a small number of subsets. One way to do this is to take a high hit count set of candidate discriminants, such as derived by the histogram procedure,  
15 and determine which from among them are "important" terms (importance being inferred, for example, from frequency of occurrence in the record, use in a title, etc.) that appear in a small percentage of the retrieved results, but are conspicuously absent from the others. That is, in some  
20 records, the term is important, but the term does not appear in all the records. In the above example of the curly haired dog breed, the name of the breed to which the record relates would be important in records that related

to the breed and absent from records unrelated to that breed. The search engine could then show a list of such discriminants, many of which might include breed names.

5 The procedure of Fig. 24 begins with a large number of low-confidence results being returned by a search process in step S310. In step S315, discriminants are identified in the search results and selected for relevance to the user's state in step S320. If there are any discriminants that are identified as relevant S325, a  
10 question is presented to the user in step S330, input is received in step S335 and a new query generated in step S340. If no relevant discriminants are found, the attempt may be aborted, or a more user interaction-intensive process based on arbitrary discriminants followed.  
15 Relevance of discriminants may be determined by consulting the user preference base. Since queries may not contain much information from the preference profile, the candidate discriminants may be used as a probe of the profile database to identify profile content that may be relevant  
20 to the search. Lexical dictionaries may be used in this context to expand terms in the profile.

Referring to Fig. 25, a procedure for using a dictionary to expand query terms is shown. In step S345,

one or more terms that is the genus of a search term or  
terms is generated and applied in generating a new query or  
queries at step S375. In step S350, at the same time, one  
or more new "where found" terms are generated and applied  
5 in generating a new query or queries at step S375. In step  
S355, at the same time, one or more new "how used" terms  
are generated and applied in generating a new query or  
queries at step S375. In step S360, at the same time, one  
or more new "parts of" terms are generated and applied in  
10 generating a new query or queries at step S375. In step  
S365, at the same time, one or more new "when used" terms  
are generated and applied in generating a new query or  
queries at step S375. In step S370, at the same time, one  
or more new "characteristics of" terms are generated and  
15 applied in generating a new query or queries at step S375.  
These related terms are only examples for purposes of  
illustration. Note that the generation steps S345-S370 may  
be recursive so that, for example, genera of hypernyms or  
holonyms of "characteristic of" terms may be generated as  
20 well. The procedure of Fig. 25 may be applied to terms  
characterizing the reader, the article associated with the  
MRL device, or other terms as illustrated by the procedure  
of Fig. 26. In step S380 alternative terms are generated

for the type of reader. In step S385, alternative terms  
are generated for the type of article or event identified  
by the MRL device. In step S386, other terms may be  
expanded in the same way. All expansions may be used in  
5 step S390 to generate alternate requests.

Referring to Fig. 27, a UI that may be used to  
enter particular kinds of scan requests includes controls  
for displaying various scales along which an article,  
event, or other thing can be characterized. For example,  
10 groceries can be characterized on a scale of freshness, in  
which dehydrated goods would be low and fresh produce in  
season would be highest, with frozen foods somewhere in the  
middle. A spinner type of control with up and down spin  
buttons 305 and 307 may be used to indicate the type of  
15 change from an example item scanned. Thus, a user would  
scan an item's MRL device, and then indicate his/her  
interest in something that is like it, but fresher (or  
cheaper, or easier to prepare, or healthier). A mode  
control 300 may be used to rotate among various scales such  
20 as freshness 310, cost 315, ease of preparation 320, and  
healthiness 325. The reader or service to which it is  
connected may choose the scales based on the type of  
product or event MRL device scanned. For example, the MRL

device of a movie might provide a set of scales that included scary, action, light-hearted, etc., while a grocery product might produce scales such as illustrated in Fig. 27. The scales may have multiple layers, for example  
5 a layer 325 below the healthiness scale permits the user to change more detailed characteristics, for example, salt content 340, fat content 335, and fiber content 330. Note that the lower level scales could be changed as part of a profile generation so that the user would create a personal  
10 definition of what constitutes healthiness, for example.

Fig. 28 shows a procedure for generating outputs resulting from scans only when predefined criteria are met. The user may turn this feature on or off. If a user scans an item and it does not correlate with the criteria in some  
15 predefined way, then a null display or no display is generated. The idea here is that a user's portable reader can act as an agent, bothering the user only when the user gets close to an item the user would find interesting. The configuration may require an ability to scan items from a  
20 substantial distance so the user need not do anything to obtain a response. MRL devices may be carried or worn by individuals and the present system used to indicate to the user some relevant information about the individuals

present, if they meet certain criteria. Beginning at step  
S270, the reader passively scans MRL devices in its  
vicinity. It compares each in turn to a criteria profile  
at step S272. If there is a match at step S274, a signal  
5 is generated in step S276 to indicate that result to the  
user. The signal may include a display or audio output  
indicating details of what triggered the match. If no  
match is identified, MRL devices are scanned again in step  
S270. An example scenario is as follows. A shopper is a  
10 gardening lover as indicated clearly by her/his profile.  
As the shopper passes a set of refrigerators in an  
appliance store, her/his reader signals the shopper with  
information about a refrigerator s/he just passed. The  
information includes a description of a feature of the  
15 refrigerator that allows seedlings to be incubated on top  
of the refrigerator, taking advantage of the gentle heat  
from the refrigerator's condenser.

Referring to Fig. 29, as discussed above, it is  
preferable that there be as few exceptions to types of  
20 articles for which the MRL system may be used. For  
example, it would be a disincentive to adopt an automated  
system for food inventory maintenance if some things in the  
food inventory could not be updated automatically.

Consumables could be a problem in this regard since MRL devices may not be programmable at the time and location of the preparation of a consumable, for example a tub of potato salad. Beginning with a registration step at S605, a preprogrammed MRL device having a unique identifier and information identifying and characterizing the consumable item, including an initial quantity, are stored in step S610. Then when a scan event occurs S615, the user receives a response or responses in any of the fashions described above, as appropriate. The user is given the option of updating quantity in step S620. If the user elects to do so, the user updates the quantity data in step S625 which is then stored in the correlation resource or database. If the consumable item is used up or some time to live parameter expires (e.g., potato salad has been stored long enough as to become unusable) S626, the thread is deleted and the data (correlation) thrown out. Note that the above procedure may be applied to items whose conditions change over time rather than items that are consumed. For example, a tomato plant may change over time increasing a food inventory. Also, the items may be non-food items such as lumber (e.g., board feet remaining) or pounds of nails. Also, MRL devices may be attached using

any suitable means, for example MRL devices may be created with adhesive backing or with reusable ties attached to them. MRL devices may also be molded into containers or permanently affixed to them. A display stand may hold MRL devices near produce items or they may be formed into the plastic bags that are often made available in supermarket produce areas. The data identifying the consumable can be stored by a checkout register in a store as an additional output of a vendor's inventory and/or purchase tracking. Alternatively, there may be stations that permit the user to enter the relevant information as in many European supermarkets where users weigh produce and make a selection at a terminal to print a bar code. The correlation data could be generated in the same way.

Referring to Fig. 30, quantity can be updated automatically using a device that measures removed or remaining quantity, or some other property of an article that has changed. For example, a smart scale 650 with a reader 645 built into it could be used. The article's last tare weight would be updated to indicate quantity whenever the article was placed on the scale 645 momentarily. Such a scale 645 may be built into a refrigerator and/or cupboard. The scale may have a UI 640. The update data

may be entered manually by the user, for example, the UI of a reader built into a table saw could prompt for the change in size of a board or the amount being cut off.

As discussed above, it does not matter where the correlation or other data is stored physically. Networks and Internet may connect one data object to a process just as a data bus connects physical memory or non volatile storage to a processor. Thus, in this discussion and elsewhere, where no particular mention is made of where data is stored, it is assumed not to matter and that a person of ordinary skill could easily make a suitable decision about where to store data - on a vendor's server, on a reader, at a home network server, on a third party server, etc. Thus, profile data may "follow" a user wherever the user goes. So if a user uses a reader in a public place, the user's personal profile is accessible to the processes the user employs. This assumes appropriate security devices are in place to protect the user's profile data. Also note that it has been assumed in the

discussions above, in most cases, that some sort of UI, such as those built into a handheld organizer with a touch screen, is associated with the readers discussed to allow data to be displayed and entered. The UI could be part of

the device to which the reader is attached or with which it  
is associated or it could be part of the reader. The  
details of the UI are not important, except as otherwise  
noted, and could be of any suitable type at the discretion  
5 of a designer.

It will be evident to those skilled in the art  
that the invention is not limited to the details of the  
foregoing illustrative embodiments, and that the present  
invention may be embodied in other specific forms without  
10 departing from the spirit or essential attributes thereof.  
The present embodiments are therefore to be considered in  
all respects as illustrative and not restrictive, the scope  
of the invention being indicated by the appended claims  
rather than by the foregoing description, and all changes  
15 which come within the meaning and range of equivalency of  
the claims are therefore intended to be embraced therein.
